Department of Electrical and Electronics Engineering, Bannari Amman Institute of Technology, Erode, Tamilnadu, India¹²³⁴

Abstract: The Space Vector Pulse Width Modulation (SVPWM) Technique has become one of the important PWM techniques for Three Phase Voltage Source Inverter (VSI) for the control of AC Induction Motors and Permanent magnet Synchronous Motors. The study of SVPWM technique reveals that space vector modulation technique utilizes DC bus voltage more efficiently and generates less harmonic distortion when compared to sinusoidal PWM technique. In this paper deals with the study of two-level SVPWM technique in all possible combinations of switching sequences. Here there are four possible switching sequences are compiled and analyzed the performance of three phase inverter in each switching sequences present in SVPWM. The analysis is made by using MATLAB/SIMULINK software and its performance was analyzed by its various parametric measures. The performance parameters to be considered in all four possible switching sequence presents in SVPWM are DC bus utilization, Total Harmonics Distortion (THD), Switching Stress, Efficiency of the Inverter, Variations in the load voltage and current. The simulation studies reveal that the best switching sequence presents in SVPWM provides better performance to the three phase inverter by various parameter measurements. The simulation results are provided to validate the proposed model approaches.

Keywords: Space vector Pulse width Modulation (SVPWM), Three Phase Inverter, Total Harmonic Distortion (THD), Switching Stress.

I. INTRODUCTION

Three phase voltage source inverters are widely used in variable speed AC motor drive applications since they provide variable voltage and variable frequency output through pulse width modulation control [1][2]. The most widely used PWM method is the carrier-based sine-triangle PWM method due to simple implementation in both analog and digital realization [2][3]. However in this method the DC bus utilization is low (0.5Vdc). This has led to the investigation into other techniques with an objective of improving in the DC bus utilization [1][3]. The PWM technique termed as Space Vector PWM based on space vector theory was proposed by de Broeck et.al (1988) and Ogasawara et.al (1989) which offers superior performance compared to the carrier –based sine-triangle PWM technique I terms of higher DC bus utilization and better harmonics performance[3]. Further, this technique offers easier digital realization. The research in PWM schemes has intensified in the last few decades. The main aim of any modulation technique is to obtain a variable output with a maximum fundamental component and minimum harmonics [3][4].

The problem of underutilization of the DC bus voltage led to the development of the Third order harmonic-injection PWM (THIPWM) and Space Vector PWM (SVPWM) [5][6]. In 1975, Buja developed this improved sinusoidal PWM technique which added a third –order harmonic content in the sinusoidal reference signal leading to a 15.5% increase in the utilization rate of the DC bus voltage. In 1988, Van Der Broeck developed the SVPWM technique which has also increased the utilization of DC bus voltage by 15.5%. Here these two techniques have similar results, but their methods of implementation are completely different [7][8]. With the development of microprocessors SVPWM has become one of the most important PWM methods for three phase inverter [9][10][11]. The maximum peak fundamental magnitude of the SVPWM technique is about 90.6% increase in the maximum voltage compared with conventional sinusoidal modulation [12][17].

In this paper having some detailed discussion about 2-level SVPWM based three phase voltage source inverter. In all the research papers discussed the performance analysis of three phase voltage source inverter by only one possible switching sequence in 2-level SVPWM. But there are four possible switching sequences are there in 2-level SVPWM. This paper tries to focus on the performance characteristics of three phase voltage source inverter in all four possible switching sequences. The MATLAB/SIMULINK is used to analyze its performance and compared its results. The result parameters are DC bus utilization, efficiency of the inverter, load voltage and load currents.
The paper organized in ten sections. Section II gives small introduction recording SVPWM principle’s. Section III introduces various steps involved in the switching time calculations. Section IV introduces the first possible switching sequence and its switching time calculation and its output waveforms. Section V introduces the second possible switching sequence and its switching time calculation and its output waveforms. Section VI introduces the third possible switching sequence and its switching time calculation and its output waveforms. Section VII introduces the fourth possible switching sequence and its switching time calculation and its output waveforms. Section VIII shows the comparative results of all the four possible switching sequences. Section IX shows the extension of the proposed scheme to the Z-source and T-source inverters. Section X concludes the paper.

II. SVPWM PRINCIPLE’S

Space Vector Modulation (SVM) was originally developed as a vector approach to pulse width modulation (PWM) for three phase inverter. It is a more sophisticated technique for generating sine wave that provides a higher voltage to the motor with lower harmonic distortion [13]. The main aim of any modulation technique is to obtain variable output having a maximum fundamental component with minimum harmonics. SVPWM method is an advance: computation intensive PWM method and possibly the best techniques for variable frequency drive applications. The principle of pulse width modulation is explained by using the figure-1[18]. The figure-1 (a) shows a circuit model of a single phase inverter with a center-tapped grounded DC bus. The figure-1 (b) illustrates principles of pulse width modulation.

From the figure-1 (b), the inverter output voltage is determined by the following ways.

1. When $V_{\text{control}} > V_{\text{triangle}}$ means $V_{AO} = V_{DC}/2$
2. When $V_{\text{control}} < V_{\text{triangle}}$ means $V_{AO} = -V_{DC}/2$

Also the inverter output voltage has the following features.

1. PWM frequency as same as the $V_{\text{triangle}}$ frequency.
2. Amplitude is controlled by the peak value of $V_{\text{triangle}}$.
3. The fundamental frequency is controlled by the frequency of $V_{\text{control}}$.
4. Modulation index (M) is defined as

$$M = \frac{V_{\text{control}}}{V_{\text{triangle}}}; 0 \leq M \leq 1$$

The circuit model of a typical three phase voltage source inverter is shown in figure-2. $S_1$ to $S_6$ are the sin’s power switches that shape the output, which are controlled by the switching variables a, a’, b, b’, c, and c’. When an upper switch (a, b, c) are switched ON ie) a, b and c = 1, the corresponding lower switches (a’, b’, c’) switched OFF myself ie) a’, b’ and c’ = 0. The upper switches and lower switches are complimentary to each other. Therefore the ON and OFF states of the upper and lower switches determines the output voltages [18]. The SVPWM is a different approach from PWM modulation based on space vector representation of the voltage in the $\alpha-\beta$ plane.

The space vector concept, which is derived from the rotating field of the induction motor, is used to modulate the inverter output voltage. In the modulation technique the three phase quantities can be transformed into their equivalent two-phase quantity either in synchronously rotating frames or stationary frame. From these two-phase components, the reference vector magnitude can be found and used for modulating the inverter output [6] [13] [16] [19]. The process of obtaining the rotating space vector is explained in the following section. Considering the stationary reference frame, let the three phase sinusoidal voltage component be

- $V_a = V_\text{msin}wt$
- $V_b = V_\text{msin}(wt-2\pi/3)$
- $V_c = V_\text{msin}(wt-4\pi/3)$  \[1\]

When these three phase voltages are applied to the AC machine it produces a rotating flux in the air gap of the
AC machine. This rotating resultant flux can be represented as a single rotating voltage vector. The magnitude and angle of the rotating vector can be found by means of Clark’s transformation as shown in figure 3. This gives the relationship between the abc reference frame to the stationary reference frame [18].

![Image](https://via.placeholder.com/595x841)

**Figure-3** The relationship between abc reference frame to the stationary dq reference frame

\[ f_{dqo} = K_s f_{abc} \]  \[ K_s = \begin{bmatrix} 1 & -1/2 & -1/2 \\ 0 & -\sqrt{3}/2 & -\sqrt{3}/2 \\ 1/2 & 1/2 & 1/2 \end{bmatrix} \]

where 

\[ f_{dqo} = [f_a f_q f_o]^T \]

and “f” denotes either a voltage or a current variable.

The relationship between the switching variable vector \([a b c]^T\) and the line-to-line voltage vector \([V_{ab} V_{bc} V_{ca}]^T\) is given by

\[
\begin{bmatrix} V_{ab} \\ V_{bc} \\ V_{ca} \end{bmatrix} = \frac{V_{dc}}{3} \begin{bmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \\ -1 & 0 & 1 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix} \]

Also the relationship between the switching variable vector \([a b c]^T\) and the phase voltage vector \([V_{an} V_{bn} V_{cn}]^T\) is given by

\[
\begin{bmatrix} V_{an} \\ V_{bn} \\ V_{cn} \end{bmatrix} = \frac{V_{dc}}{3} \begin{bmatrix} 2 & -1 & -1 \\ -1 & 2 & -1 \\ -1 & -1 & 2 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix} \]

As described in Figure-3. This transformation is equivalent to an orthogonal projection of \([a b c]^T\) onto the two-dimensional perpendicular to the vector \([1 1 1]^T\) (the equivalent d-q plane) in a three-dimensional coordinate system. As a result, six non-zero vectors and two zero vectors are possible. Six non-zero vectors \((V_1 \text{ to } V_6)\) sharp the axes of a hexagonal as depicted in Figure-3, and supply power to the load. The angle between any adjacent two non-zero vectors is 60 degrees.
Meanwhile, two zero vectors \((V_0\) and \(V_7\)) and are at the origin and apply zero voltage to the load. The eight vectors are called the basic space vectors and are denoted by \((V_0, V_1, V_2, V_3, V_4, V_5, V_6, V_7)\). The same transformation can be applied to the desired output voltage to get the desired reference voltage vector, \(V_{ref}\) in the \(d-q\) plane. The objective of SVPWM technique is to approximate the reference voltage vector \(V_{ref}\) using the eight switching patterns. One simple method of approximation is to generate the average output of the inverter in a small period \(T\) to be the same as that of \(V_{ref}\) in the same period [6] [13]. The following figure-5 represents the identification of sectors by vector locations. This figure-5 represents all the eight vectors and sectors with 60° displacement with each other.

![Figure-5 Basic switching vectors and sectors](image)

### III. VARIOUS STEPS INVOLVED IN SWITCHING TIME CALCULATION IN SVPWM

By referring the above introductory part of SVPWM principle’s, the SVPWM can be implemented in the following steps. The first step is to generate three phase waveforms \(V_a, V_b, V_c\) by referring the equation 1.

\[ V_a = V\sin(wt) \]
\[ V_b = V\sin(wt-2\pi/3) \]
\[ V_c = V\sin(wt-4\pi/3) \]

Where \(w = 2\pi f\) and \(f = 50\) Hz.

The second step is to transform abc parameters into \(dq\) parameters

\[ V_d = V_a \cos 0^\circ + V_b \cos 120^\circ + V_c \cos 240^\circ = V_d - \frac{\sqrt{3}}{2} V_b \]
\[ V_q = V_a \cos 270^\circ + V_b \cos 30^\circ + V_c \cos 150^\circ = 0 + \frac{\sqrt{3}}{2} V_b \]

\[
\begin{bmatrix}
V_d \\
V_q
\end{bmatrix} = \frac{2}{3} \begin{bmatrix}
1 & -\frac{1}{2} & -\frac{1}{2} \\
0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} \\
0 & 0 & 0
\end{bmatrix} \begin{bmatrix}
V_a \\
V_b \\
V_c
\end{bmatrix}
\] \[ [5] \]

The third step is to calculate \(V_{ref}\) magnitude and angle \(\alpha\) values from equation 5.

\[ V_{ref} = V_d + jV_q = \sqrt{(V_d^2 + V_q^2)} \]

\[ \alpha = \tan^{-1}\left(\frac{V_q}{V_d}\right) \]

The fourth step is to identify the sector in which the reference voltage space vector is present. It is necessary to know in which sector the reference output lies in order to determine the switching time and sequence. The identification of the sector where the reference vector is located is straightforward. The phase voltage corresponding to eight switching states: six non-zero vectors and two zero vectors at the origin. Depending on the reference voltages, the angle of the reference vector can be determined the sector as per the table-2 [18].

<table>

</tr>
<tr>
<td>6</td>
<td>(300^\circ &lt; \alpha \leq 360^\circ)</td>
</tr>
</tbody>
</table>

The fifth step is switching time calculation: to determine the time duration of \(T_a, T_b\) and \(T_0\). Consider the reference vector in sector 1 as shown in figure-6.

The volt-second product in sector-1 can be written as

\[ V_{ref} \times T_s = V_1 \times T_1 + V_2 \times T_2 + V_0 \times T_0 \]

Where

\[ V_{ref} = [V_a] = V_a \cos \alpha + j[V_a] \sin \alpha \]

\[ V_1 = \frac{2}{3} V_a + j(0), \]

\[ V_2 = \frac{2}{3} V_a \cos \left(\frac{\pi}{3}\right) + j\left(\frac{2}{3}\right)V_a \sin \left(\frac{\pi}{3}\right) \]

The equation-7 can be written as

\[ T_1 \left[ \sin \alpha \begin{bmatrix} \cos \alpha \\ 0 \end{bmatrix} + T_2 \begin{bmatrix} 0 \\ \sin \alpha \end{bmatrix} \right] = 0 + T_0 \]

From equation 8

\[ T_1 \left[ 2V_a \sin \alpha \right] = T_2 \left[ \frac{2}{3} V_a \sin \frac{\pi}{3} \right] \]

\[ \Rightarrow \frac{T_1}{T_2} = \frac{\frac{2}{3} V_a \sin \frac{\pi}{3}}{2V_a \sin \alpha} \]

\[ \Rightarrow T_1 = T_2 \left( \frac{\frac{2}{3} V_a \sin \frac{\pi}{3}}{2V_a \sin \alpha} \right) \]

\[ \Rightarrow T_1 = T_2 \left( \frac{\alpha}{\frac{\pi}{3}} \right) \]

where \(\alpha = \frac{V_1}{V_a}\)
Substitute equation 9 in equation 8 we get a T1

\[ T_1 = T_s \cdot \alpha \cdot \sin \left( \frac{\pi}{3} - \alpha \right) \]  

now, \[ T_0 = T_s - (T_a + T_b) \]  
because, \[ T_s = T_a + T_b + T_0 \]  

Now generalizing the switching time calculation for entire 6 sectors, therefore

\[ T_a = \frac{\sqrt{3} V_{ref}}{V_{dc}} \cdot \alpha \cdot \sin \left( \frac{n\pi}{3} - \alpha \right) \]

\[ T_b = \frac{\sqrt{3} V_{ref}}{V_{dc}} \cdot \alpha \cdot \sin \left( \alpha - \frac{(n-1)\pi}{3} \right) \]

\[ T_0 = T_s - T_a - T_b \]  

Where n=1, 2...6 and α = 0 to 60°. The figure-6 shows the reference vector as a combination of adjacent vectors at sector-1. The following table-3 gives the exact location of Vref and its Dwell time in each sector [18].

<td>( T_0 \geq T_0 )</td>
</tr>
</tbody>
</table>

IV. THE FIRST POSSIBLE SWITCHING SEQUENCE AND ITS SWITCHING TIME CALCULATIONS

With the space vectors, selected and the switching times or dwell times calculated, the next step is to arrange possible switching sequences. In general the switching sequence design for a given \( V_{ref} \) is not unique, but it should satisfy the following two requirements for the minimization of the device switching frequency [13] [14].

a) The transition from one switching state to the next involves only two switches in the same inverter leg, one being switched ON and other being switched OFF.

b) The transition of \( V_{ref} \) moving from one sector in the space vector diagram to the next requires no or minimum number of switches.

The figure-7 space vector diagram for two-level inverter shown below should satisfy the above two requirements. This space vector diagram is common to all the four possible switching sequences. Only changes in this space vector diagram are the various possibilities of reference vector rotation in each sectors. The first possible switching sequence in each sector is like, starting with \( [000] \) switching sequence and also ends with \( [000] \) switching sequence. This will be shown in figure-7.1

The seven segments switching sequence and switching time calculation for each switch for each sector is shown in figure 8.1 to 8.6. Figure 8.1 to 8.6 shows a typical seven segment switching sequence and inverter output waveforms for \( V_{ref} \) in each sectors. Here \( V_{ref} \) is synthesized by \( V_1, V_2, \) & \( V_0 \). The sampling period \( T_s \) is divided into seven segments for the selected vectors. The following can be observed.

The dwell time for the seven segments adds up to the sampling periods, \( T_s = T_a + T_b + T_0 \). The design
requirement (a) is satisfied. For instance the transition from [000] to [100] is accomplished by turning S1 ON and S4 OFF, which involves only two switches. The redundant switching state Error! Bookmark not defined. are utilized to reduce the number of switching’s per sampling period. For T0/4 segment in the center of the sampling period, the switching state [111] is selected, whereas for the T0/4 segments on both sides, the state [000] is used.

Each of the switches in the inverter turns ON and OFF once per sampling period. The switching frequency \( f_{sw} \) of the devices are thus equal to the sampling frequency \( f_{sp} \), ie) \( f_{sw} = f_{sp} = 1/T_s \) [13] [14].

The performance parameters of the three phase two level inverters are measured and shown in the figure-9.1 to 9.16.

Figure-8.1 to 8.6 shows seven segments switching sequences for \( V_{ref} \) in sector 1 to 6.

V. THE SECOND POSSIBLE SWITCHING SEQUENCE AND ITS SWITCHING TIME CALCULATIONS

The first possible switching sequence in each sector is like, starting with [111] switching sequence and also ends with [111] switching sequence. This will be shown in figure-10. The seven segments switching sequence and switching time calculation for each switch for each sector is shown in figure 11.1 to 11.6. Figure 11.1 to 11.6 shows a typical seven segment switching sequence and inverter output waveforms for \( \bar{V}_{\text{ref}} \) in each sectors. Here \( \bar{V}_{\text{ref}} \) is synthesized by \( V_1, V_2 \& V_0 \). The sampling period \( T_s \) is divided into seven segments for the selected vectors. The following can be observed. The dwell time for the seven segments adds up to the sampling periods, \( T_s = T_a + T_b + T_0 \). The design requirement (a) is satisfied. For instance the transition from [111] to [110] is accomplished by turning S5 ON and S2 OFF, which involves only two switches [13] [14].

Figure-11.1 to 11.6 shows seven segments switching sequences for \( \bar{V}_{\text{ref}} \) in sector 1 to 6.
The redundant switching state is utilized to reduce the number of switching’s per sampling period. For T0/4 segment in the center of the sampling period, the switching state [000] is selected, whereas for the T0/4 segments on both sides, the state [111] is used. Each of the switches in the inverter turns ON and OFF once per sampling period. The switching frequency $f_{sw}$ of the devices are thus equal to the sampling frequency $f_{sp}$, i.e. $f_{sw} = f_{sp} = 1/T_s$ [13][14].

The performance parameters of the three phase two level inverters are measured and shown in the figure 12.1 to 12.16.
VI. THE THIRD POSSIBLE SWITCHING SEQUENCE AND ITS SWITCHING TIME CALCULATIONS

The third possible switching sequence in each sector is like, starting with [000,111] switching sequence and also ends with [000,111] switching sequence. This will be shown in figure-13. The seven segments switching sequence and switching time calculation for each switch for each sector is shown in figure 14.1 to 14.6. Figure 14.1 to 14.6 shows a typical seven segment switching sequence and inverter output waveforms for \( V_{\text{ref}} \) in each sectors. Here \( V_{\text{ref}} \) is synthesized by \( V_1, V_2 \) & \( V_0 \). The sampling period \( T_s \) is divided into seven segments for the selected vectors. The following can be observed.

Figure-14.1

Figure-13 Space vector diagram for two level inverter
The dwell time for the seven segments adds up to the sampling periods, $T_s = T_a + T_b + T_0$. The design requirement (a) is satisfied. For instance, the transition from [000,111] to [100,110] is accomplished by turning S1 ON and S5 OFF, which involves only two switches. The redundant switching state Error! Bookmark not defined. are utilized to reduce the number of switching’s per sampling period. For T0/4 segment in the center of the sampling period, the switching states [000, 111] are selected, whereas for the T0/4 segments on both sides, the states [111,000] are used. Each of the switches in the inverter turns ON and OFF once per sampling period. The switching frequency $f_{sw}$ of the devices are thus equal to the sampling frequency $f_{sp}$, i.e. $f_{sw} = f_{sp} = 1/T_s$ [13] [14]. The performance parameters of the three phase two level inverters are measured and shown in the figure-15.1 to 15.16.
VII. THE FOURTH POSSIBLE SWITCHING SEQUENCE AND ITS SWITCHING TIME CALCULATIONS

The fourth possible switching sequence in each sector is like, starting with \([111,000]\) switching sequence and also ends with \([111,000]\) switching sequence. This will be shown in figure-16. The seven segments switching sequence and switching time calculation for each switch for each sector is shown in figure 17.1 to 17.6. Figure 17.1 to 17.6 shows a typical seven segment switching sequence and inverter output waveforms for \(V_{\text{ref}}\) in each sectors. Here \(V_{\text{ref}}\) is synthesized by \(V_1, V_2, V_0\). The sampling period \(T_s\) is divided into seven segments for the selected vectors. The following can be observed.

The dwell time for the seven segments adds up to the sampling periods, \(T_s = T_a + T_b + T_0\). The design requirement (a) is satisfied. For instance the transition from \([111,000]\) to \([110,011]\) is accomplished by turning S1 ON and S5 OFF, which involves only two switches. The redundant switching state are utilized to reduce the number of switching’s per sampling period. For T0/4 segment in the center of the sampling period, the switching states \([000, 111]\) are selected, whereas for the T0/4 segments on both sides, the states \([111,000]\) are used. Each of the switches in the inverter turns ON and OFF once per sampling period. The switching frequency \(f_{sw}\) of the devices are thus equal to the sampling frequency \(f_{sp}\), i.e. \(f_{sw} = f_{sp} = 1/T_s\) [13] [14]. The performance parameters of the three phase two level inverters are measured and shown in the figure-18.1 to 18.16.

VIII. COMPARATIVE RESULTS OF ALL FOUR POSSIBLE SWITCHING SEQUENCES

The main aim of any modulation technique is to obtain variable output having maximum fundamental component with minimum harmonics. The objective of SVPWM technique is to enhance the fundamental output voltage and the reduction of harmonic content in three phase voltage source inverter. In this paper having different possibilities of switching schemes present in two level SVPWM are compared in terms of THD. The Simulink model has been developed for SVPWM modulated two level three phase voltage source inverter. The simulation work is carried in MATLAB/SIMULINK.

The simulation parameters used are; DC input voltage = 100V, fundamental frequency = 50Hz, ODE solver = ode45 (Dormand-Prince), switching frequency = 12 kHz, modulation index = 0.87, load type = constant Z, load = star connected R-L load, active power = 1kW, inductive reactive power = 1000e-3VAR, filter = second order filters. The performance of two level SVPWM modulated three phase VSI is analyzed by considering parameters. The comparative statements of each parameter are given below.

IX. SVPWM TECHNIQUE FOR Z-SOURCE AND T-SOURCE INVERTERS

All the above section represents the basic concepts recording SVPWM, the various switching sequence in SVPWM and the performance of 2-level three phase voltage source inverter. The same concepts can be represented in the Z - Source inverter (ZSI) and T-Source inverter (TSI) also. The procedure for switching sequence in ZSI and TSI are same as three phase voltage source inverter except the introduction of a shoot though zero state in ZSI. The following subsequent paper should explain these concepts in details.

X. CONCLUSION

The SVPWM technique can only be applied to a three-phase inverter and it increases the overall system efficiency. The SVPWM is used for controlling the switching of the machine side converter. Advantages of this method include a higher modulation index, lower switching losses, and less harmonic distortion compared to SPWM. Therefore SVPWM research has been widespread in recent years, making it one of the most popular methods for three-phase inverters because it has a higher fundamental voltage output than SPWM for the same DC bus voltage. The SVPWM is significantly better than SPWM by approximately 15.5%. However, the SVPWM technique is complex in implementation, especially in the over-modulation region. But SVPWM technique has become the most popular and important PWM technique for three phases VSI for the control of AC induction. This paper has provided a thorough review of the each technique with a special focus on the operation of SVPWM in all the four possible switching sequences. In this paper, Simulink models for all four switching sequences has been developed and tested in the MATLAB/SIMULINK environment. This paper discusses the advantages and drawbacks of each switching sequence and their simulation results are compared and analyzed by plotting the output harmonic spectra of various output voltages and computing their total harmonic distortions (THD). As seen from the simulation results the DC bus utilization will be same for all the four possible switching sequences, but the THD will be varied for every switching sequence. From the simulation results we can come to the conclusion like the methods-I and III switching sequence having less THD when compared to the other two methods of switching sequence. In the future researches there are some possibilities are available for implementing the same switching sequence in three phase ZSI and TSI. Definitely the performance of ZSI and TSI will be varied with respect to its different switching sequences.
